Simulating hard probes in the early-stages of heavy-ion collisions

Dienstag, 28. März 2023 12:10 (20 Minuten)

We study the impact of the Glasma fields, used to describe the very-early stage of heavy-ion collisions, on the transport of hard probes, namely heavy quarks and jets. We perform numerical simulations of the strong classical fields using techniques from *real-time lattice gauge theory*. The resulting fields are used as background for the classical transport of ensembles of particles, described by *Wong's equations*. We develop a numerical solver for the transport of the probes, based on *colored particle-in-cell* methods.

We focus on the dynamics of heavy quarks and jets in the classical colored fields. To quantify the effect of the Glasma, we extract *momentum broadening* of hard probes and evaluate the *anisotropy* transfer from the Glasma to the probes. We investigate other ways to measure the imprint of the Glasma, such as *two-particle angular correlations* of quark pairs or gauge invariant correlators of color Lorentz forces exerted on the probes.
